

Build a durable AI workflow

Mistral AI

Workflows move AI pipelines from a script to a durable system.

Your code stays in your environment. Mistral handles orchestration, state, retries, and observability so multi-step work can survive crashes and long waits.

Local code

The worker runs where your project, dependencies, and secrets already live.

Managed state

The platform tracks workflow runs and resumes from completed activities.

Visible execution

Runs can be launched and watched from Console or from the Makefile.

The quickstart is a five-part loop: scaffold, inspect, run, trigger, verify.

01 Scaffold Create a ready-to-run Python project with the workflows CLI.	02 Inspect Read the example workflow and its activity boundary.	03 Worker Connect to Mistral, register the workflow, wait for tasks.	04 Trigger Start an execution from Makefile or Console.	05 Verify Confirm the returned result and stop the worker.
---	--	---	--	---

Start with three requirements, then let the CLI create the project shell.

Required

Mistral API key, Python 3.12+, and uv with uvx available.

```
uvx mistralai-workflows-cli setup
```

```
# Open the generated directory  
cd my-workflow
```

Generated project

The default directory is my-workflow, with environment configuration for the API key.

Activities are durable steps; the workflow definition is the triggerable unit.

If the process crashes mid-run, Mistral can replay from the last completed activity.

```
@workflows.activity()
async def greet(name: str) -> str:
    return f"Hello, {name}!"

@workflows.workflow.define(
    name="hello-world"
)
class HelloWorldWorkflow:
    @workflows.workflow.entrypoint
    async def run(self, input):
        return await greet(input.name)
```

The worker is the bridge between local execution and managed orchestration.

Keep the worker open, then start a run from a second terminal or Console.

```
make start-worker
```

```
make execute workflow=hello-world  
input='{"name":"World"}'
```

```
{  
  "result": "Hello, World! Welcome to Mistral  
Workflows."  
}
```

Console path

Workflows sidebar -> hello-world -> Start Workflow -> pass JSON input -> Executions tab.

Troubleshooting

If the worker shows a connection error, confirm the API key and that the worker is still running.

The minimal workflow is small, but the operating model is production-shaped.

Define

Name the workflow so it can be registered and triggered.

Isolate

Mark durable steps with the activity decorator.

Run

Use the worker as the long-lived task executor.

Observe

Follow executions from Console and verify outputs.

NEXT STEPS

Extend the skeleton into real AI work.

Use the quickstart as the smallest reliable loop, then move into core concepts, cookbook examples, and durable agent patterns.
